In the Specification

Please amend the paragraph beginning on page 5, line 8 as follows:

In FIG. 2, each drawer D_i has a "viewable area" A_i (i=0, 1, 2, ..., N), wherein $A_i \geq 0$. The "viewable area" A_i is an area of the drawer D_i that is visible (e.g., not hidden) to a person (i.e., "user" or "viewer") who is viewing the data display structure **18**. If no area of the drawer D_i is visible to the user, then $A_i=0$. The viewable area A_i may change dynamically as the drawer D_i is "being opened" or "being closed". The drawer D_i (i=1, 2, ..., N) is being opened or is being closed if D_i is being moved (e.g., by dragging the tab T_i) in a direction **5** or **6**, respectively. Note that an absence of tabs does not limit the capability of opening or closing the drawers in the data display structure **18**. For example, the drawer D_i (i=1, 2, ..., N) may be further opened or further closed ~~closed~~ by dragging a bordering edge E_i of the drawer D_i instead of by dragging the tab T_i. If D_i is being moved in the direction **5**, then D_i is being moved in a direction that covers D_0 to a greater extent. If D_i is being moved in the direction **6**, then D_i is being moved in a direction that covers D_0 to a lesser extent. Definitionally, D_i (i=1, 2, ..., N) is adapted to being opened if D_i is capable of being opened (i.e., capable of being moved in the direction **5**), and D_i is adapted to being closed if D_i is capable of being closed (i.e., capable of being moved in the direction **6**). An action of "opening" D_i subjects D_i to being opened; i.e., being moved in the direction **5**. An action of "closing" D_i subjects D_i to being closed; i.e., being moved in the direction **6**.
